

REVIEW ARTICLE

ORS – Which one to use?

B.S. Ramakrishna

Introduction

Acute diarrheal disease continues to claim the lives of an estimated half a million children annually in India and of nearly two million children worldwide. (1) The global reduction in mortality from approximately 5 million diarrheal deaths annually twenty years ago, (2) is attributed to the widespread utilization of oral rehydration solution (ORS). The introduction of ORS, hailed as one of the most significant medical advances of the twentieth century, allowed correction of dehydration and prevention of mortality. (3) ORS use was based on the fact that cyclic AMP and other diarrhea mediators inhibited sodium chloride absorption, but not glucose-linked sodium absorption. However, conventional glucose-based ORS did not reduce duration or severity of diarrhea and paradoxically increased diarrhea in some children. (4) This led to attempts to identify solutes that would stimulate sodium absorption and at the same time reduce diarrhea. Though amino acid-linked sodium absorption was another potential target for ORS development, a number of studies that compared amino acid-based ORS with glucose-based ORS did not reveal any superiority of the former. In the 1980s, cereal-based ORS was also widely tested as an alternative to the glucose-based ORS. Cereal-based ORS was very effective, and of these only rice-based ORS survived over time. Though rice-based formulations were identified for home preparation and use, there is at least one commercially available formulation that uses rice as the glucose donor. An early meta-analysis of 13 clinical trials suggested that, compared to glucose-ORS, rice-ORS reduced stool output by about 18% in children with non-cholera diarrhea. (5) This meta-analysis also suggested that most of the effectiveness of rice- or other cereal-based ORS was due to the low osmolality of the ORS used. Hypo-osmolar ORS was particularly effective in the subgroup without rotavirus. Following customary practice in many parts of the world, food intake was generally withheld during diarrhea for fear of aggravating symptoms. However, in the 1980s, work primarily led by pediatricians in Bangladesh showed that early refeeding was effective in reducing diarrhea in children and this became a cornerstone of therapy. Bhan et al in 1994 compiled a summary of several attempts to improve ORS for diarrhea in children and concluded that rice-based ORS, maltodextrin-containing and amino acid-containing ORS were not superior to glucose-based ORS for acute non-cholera diarrhea, provided that feeding was promptly resumed after initial rehydration of the child. (6) Several trials of rice-based ORS continued to be published, and the most recent meta-analysis concluded that rice-based ORS reduced mean stool output by 51-67% in adults and children with cholera, but was not significantly better than glucose ORS in children with non-cholera diarrhea, where mean stool output was only 4 ml/kg lower than glucose ORS. (7)

Following the introduction of ORS in the late 1960s by various groups in the Philippines, in Dhaka and in Kolkata, (8,9) the ORS formulation that was approved

by the World Health Organization in 1975 is shown in Table 1. This ORS was developed following studies of fecal electrolyte composition in cholera, a disease that causes extreme dehydration and affects adults more often than children. Common cause of diarrhea in children such as rotavirus infection is characterized by lesser degree of fecal sodium loss. Pediatricians in Europe using the original glucose-ORS for children with diarrhea quickly recognized that use of this ORS sometimes caused hypernatremia. This may have been due to the fact that the children were given only ORS and not allowed supplemental water, whereas the standard practice elsewhere was to allow free intake of water in addition to ORS.

Table 1. Composition of standard oral rehydration solution and new reduced osmolality ORS as recommended by the World Health Organization.

Ingredient	Standard WHO ORS mmol/l	Reduced osmolality ORS mmol/l
Glucose	111	75
Na+	90	75
K+	20	20
Cl-	80	65
Citrate	10	10
Osmolarity mOsm/kg	311	245

By the 1980s, European pediatricians began to use an ORS that had a lower content of sodium (usually 60 mmol/l) and lower osmolality, and this was endorsed by the European associations. (10) At around this time, a scientific basis for reducing the osmolality of ORS also began to emerge. Since the 1960s, it was known that reducing the osmolality of a solution that was ingested increased the absorption of water from that solution. (11) In the 1980s, attempts were made to study the physiological effects of reduced osmolality in the secreting intestine. Rolston and others showed that reducing the osmolality improved small intestinal water absorption from ORS in animals with experimentally induced diarrhea. (12,12) Subsequently, Rolston also showed that reducing the sodium concentration of ORS led to better water absorption in human volunteers in south India and would be appropriate in countries with a high prevalence of tropical enteropathy. (14)

These experimental studies were followed by a number of clinical studies in patients with diarrhea, including a multi-center international trial. (15) Meta-analysis of these studies concluded that, compared to WHO standard ORS, hypo-osmolar ORS was associated with fewer unscheduled intravenous fluid infusions, lower stool volumes and less vomiting. (16,17) These differences are shown in Table 2.

Based on these studies, the UNICEF and WHO organized a meeting of experts in New York in July 2001 which suggested a consensus reduced osmolarity ORS formulation.(18) The WHO officially incorporated this change in the recommended composition of ORS to this low sodium, low glucose, low osmolarity solution in 2002.

Table 2. A summary of the meta-analysis of trials with reduced osmolarity ORS in children with diarrhea. 15 trials involving 2397 patients were analyzed. (Hahn et al, 2001).

Outcome variable	No. of trials	Odds ratio	95% confidence interval
Unscheduled IV Treatment	9	0.61	0.47-0.81
Vomiting	6	0.71	0.55-0.92
Hyponatremia	6	1.45	0.93-2.26
Stool output reduction	13	21/4%	12.3-30.5

The Journal of the American Medical Association in 2004 carried two opinion pieces, one defending the change in ORS to reduced osmolarity solution, and the other pointing out the potential problems that may be encountered with recommending a reduced osmolarity solution for universal use in all forms of diarrhea.(19,20) A meta-analysis of studies of reduced osmolarity ORS in patients with cholera concluded that its use is associated with biochemical hyponatremia when compared with standard ORS, although there were similar benefits in terms of outcomes; and that under wider practice conditions, where monitoring is likely to be difficult, caution is warranted in the use of reduced osmolarity ORS in cholera or other severe diarrhea.(21) Therefore it may be useful to have one solution (with low sodium and low osmolarity) for use in children with diarrhea, while another solution (the old WHO formula) may be more appropriate for adults with cholera.

The use of zinc to reduce diarrhea duration has been widely studied. Zinc supplementation has been found to reduce diarrhea duration and to reduce the frequency of persistent diarrhea and consequent malnutrition which complicates diarrhea in children in developing countries.(22,23) Currently the consensus is to use zinc in the form of 20 mg elemental zinc given once daily for 14 days.

Although reduced osmolarity ORS has major advantages in the treatment of children with non-cholera diarrhea, the reduction of diarrhea volume and duration is a goal that remains to be attained. Short chain fatty acids are produced in the colon by fermentation of unabsorbed carbohydrate and stimulate sodium absorption. Like glucose-linked sodium absorption in the small intestine, this absorptive process in the colon is not altered in diarrheal disease. Amylase resistant starch, found in some foods such as cereals and green banana, is fermented to short chain fatty acids in the colon and reduces diarrhea both in adults

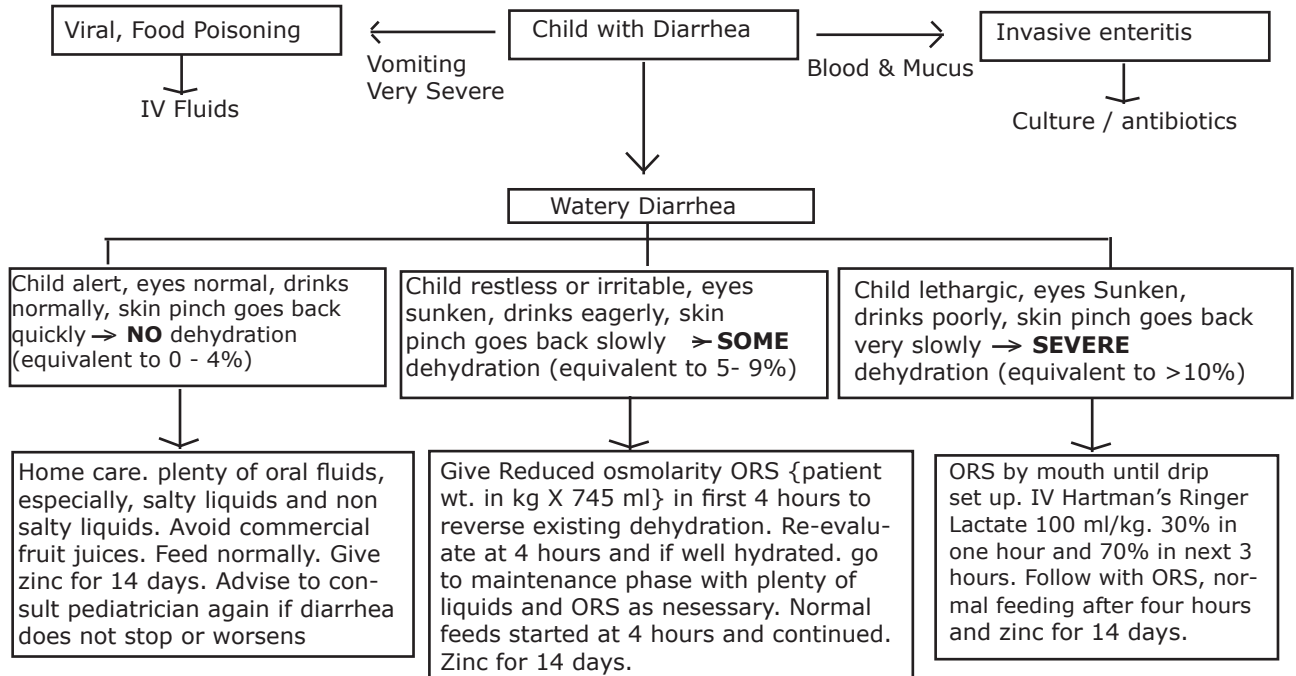

with cholera and in children with non-cholera diarrhea. (24,25)

Children presenting with acute diarrhea should be assessed as to whether they have a watery diarrhea syndrome or bloody diarrhea syndrome, and whether there is evidence of clinical dehydration. Dehydration is assessed as 'none', 'some' or 'severe' according to the WHO Management of Diarrhoea guidelines (Figure 1). Children who have severe dehydration require intravenous hydration (with Ringer lactate solution preferentially) of which 100 ml/kg is given over four hours, 30% in the first hour and the remaining 70% over three hours. Children with 'some' dehydration are presumed to have dehydration of between 5-10% of body weight and should be treated with reduced osmolarity ORS. ORS can be administered via nasogastric tube in the initial stages of rehydration in sick children who are unable to take adequate amounts of ORS. It is estimated that approximately one in every 25 children that are given ORS will go on to require intravenous hydration. Children are assessed frequently and oral intake, urine output and stool output measured. It is expected that rehydration (replacement of lost fluid) would have completed in the first four hours and the subsequent phase is maintenance of hydration, where ORS intake is matched to stool losses. The usual diet of the child is allowed after the first four hours in children with significant dehydration, and is continued without interruption in normal in children with no dehydration. The use of zinc has become commonplace and 20 mg of elemental zinc is given as suspension or tablet once daily for 14 days. The use of starchy foods is encouraged. Commercially available fruit juices have a high osmolarity and are best avoided in the initial phase of hydration of the child. Antibiotics are generally not necessary in the treatment of diarrhea in children, except in older children with severely dehydrating diarrhea where cholera is suspected or proved by dark field microscopy of the feces, or in children with blood and mucus diarrhea due to an invasive organism such as *Shigella*. Early return to normal nutritional intake is highly desirable both in terms of recovery from the current episode of diarrheal illness and in prevention of persistent diarrhea and malnutrition.
